Selected - Frequency Analysis

To break a Vigenere cipher, you can use frequency analysis. Here are the steps to follow:

1. Determine the length of the key: The first step is to find the length of the key used in the Vigenere cipher. You can do this by looking for repeating patterns in the encrypted text. If the key length is unknown, you can try different key lengths and analyze the results.

2. Divide the encrypted text into groups: Once you have the key length, divide the encrypted text into groups of that length. Each group will correspond to a letter encrypted with the same key letter.

3. Analyze the frequency of each group: Count the frequency of each letter in each group. This will give you a frequency distribution for each group.

4. Compare the frequency distributions: Compare the frequency distributions of the groups with the expected frequency distribution of the English language. The most common letters in English are E, T, A, O, I, N, S, H, R, and D. Look for similarities between the frequency distributions of the groups and the expected frequency distribution

5. Determine the key: Once you have identified the most likely letters for each group, you can determine the key by finding the shift between the encrypted letters and the corresponding decrypted letters. This shift will give you the key letter for each group.

6. Decrypt the text: Finally, use the key to decrypt the entire text by shifting each letter back to its original position

Remember that frequency analysis is not foolproof and may not always work, especially if the text has been encrypted using additional techniques to counter frequency analysis.

Block Cipher DES (Mode of Encryption)

n-bits plaintext → n-bits

$2^4 \times 4$ required key for 4-bit

$2^{10} \times 10$ required key for 10-bit encryption

$n \sim 2^n$ $2^{64} \times 64$ for 64-bit

Fiestal came up with a design

2^k

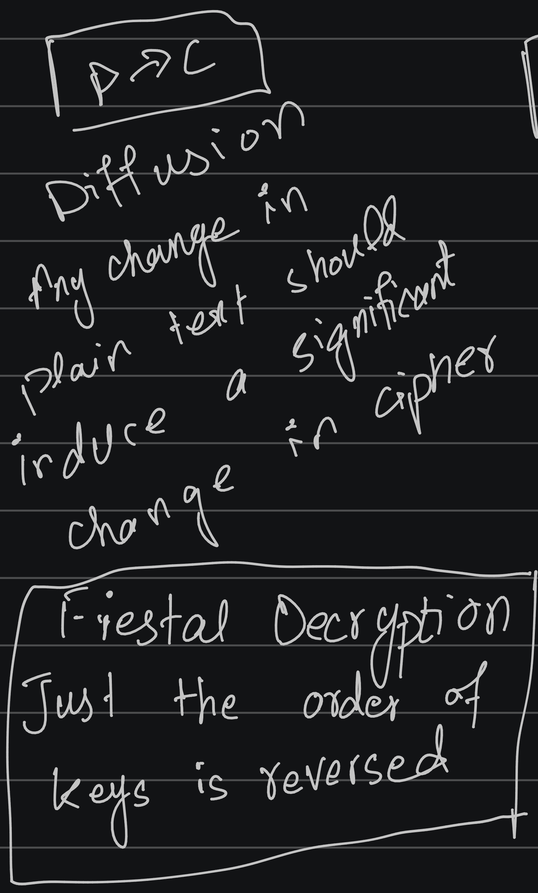
Confusion and diffusion are two fundamental concepts in cryptography, specifically in the context of block ciphers like DES.

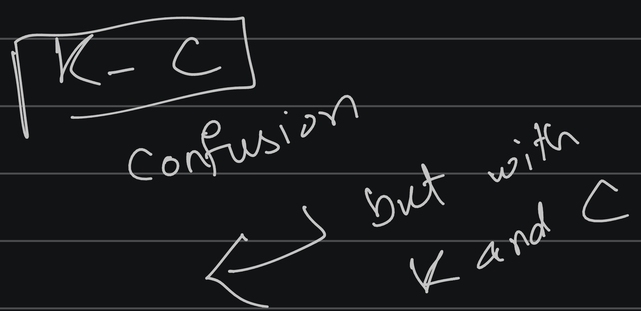
1. Confusion: Confusion refers to the process of making the relationship between the plaintext and the ciphertext as complex and obscure as possible. It involves introducing confusion by using mathematical operations, such as substitution or permutation, to ensure that even a small change in the plaintext results in a significant change in the ciphertext. This makes it difficult for an attacker to deduce any information about the plaintext from the ciphertext.

2. Diffusion: Diffusion refers to the process of spreading the influence of each plaintext bit over a large number of ciphertext bits. It aims to distribute the statistical properties of the plaintext uniformly throughout the ciphertext. Diffusion ensures that any change in the plaintext affects multiple bits in the ciphertext,

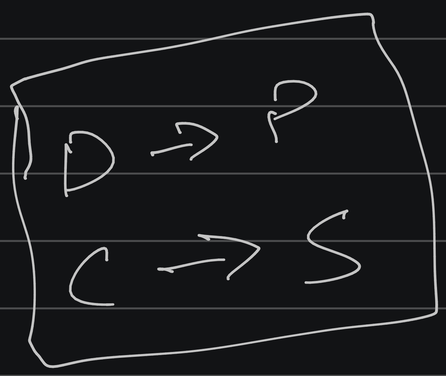
making it harder for an attacker to identify patterns or correlations.

Both confusion and diffusion are essential in achieving strong encryption. Confusion helps to hide the relationship between the plaintext and the ciphertext, while diffusion ensures that any changes in the plaintext have a widespread effect on the ciphertext. By combining these two concepts, block ciphers can provide a high level of security and resistance against various cryptographic attacks.





As for keys, if a key has majority of 0s and minority of 1s the permutation would not change the structure significantly. So you must use substitution



Plaintext cannot be substituted. The substitution boxes would give away things

1977 – 2001 DES Avalanche

birthday Paradox → 99% chance of finding a key from 50% brute force

Fri, Feb 16 Galloa Fields

- Finite Field.

→ GF(P^n)

Groups → Abelian Groups → Rings → Commutative rings → Integral domains → Fields → Finite Fields

Group (Generalize all operators)

Denoted by $\{G, \odot\}$ Usually addition & operator ko use kya jaata hai.

A group should follow some properties.

Abelian Group defined another property

Rings (Inherit properties of Groups)

→ Ring specified the use of + to groups also defined multiplicative rules.

[should always have addition property of groups]

Commutative Ring defined another multiplicative

Internal Domain

Fields (inherit A1 – A5 amd M1 – M6 from previous)

Defined another M7 property

Types of Fields

Infinite Field

Set of infinite field

Finite Fields

Include finite sets only

For example Galloa Field GF(8)

Only 8 elements

Classical Cipher aren't in Finite Fields / Different maths

GF(p) → GF(p^n) → These deal with polynomials.

Additive inverse in modulo 8

$a + b = 0$

$1 + 7 \equiv 0$ Additive inverse

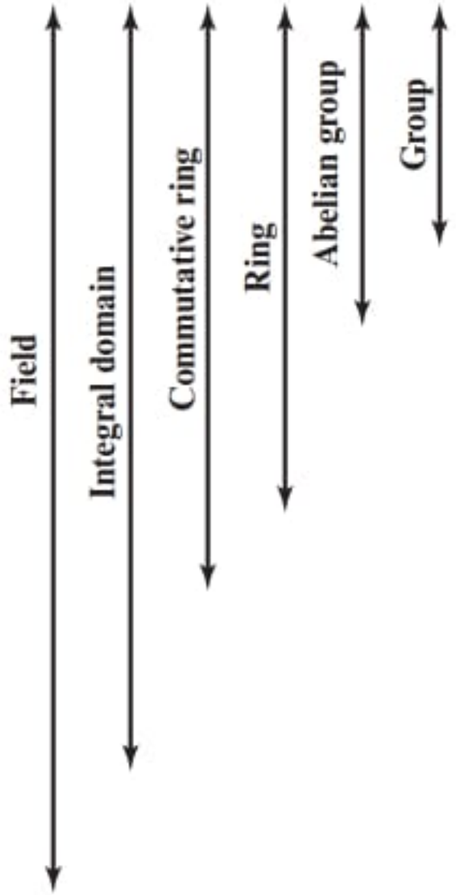
Polynomial Arithmetic:

GF(p) mai co-efficients mod p ho jatay hai

GF(p^n) → coff mod p tak jaye ga

→ coff mod p [highest power mod n]

that we are using ordinary modular arithmetic to define the operations over these fields.



(A1) Closure under addition:	If a and b belong to S, then $a + b$ is also in S
(A2) Associativity of addition:	$a + (b + c) = (a + b) + c$ for all a, b, c in S
(A3) Additive identity:	There is an element 0 in R such that $a + 0 = 0 + a = a$ for all a in S
(A4) Additive inverse:	For each a in S there is an element $-a$ in S such that $a + (-a) = (-a) + a = 0$
(A5) Commutativity of addition:	$a + b = b + a$ for all a, b in S
(M1) Closure under multiplication:	If a and b belong to S, then ab is also in S
(M2) Associativity of multiplication:	$a(bc) = (ab)c$ for all a, b, c in S
(M3) Distributive laws:	$a(b + c) = ab + ac$ for all a, b, c in S $(a + b)c = ac + bc$ for all a, b, c in S
(M4) Commutativity of multiplication:	$ab = ba$ for all a, b in S
(M5) Multiplicative identity:	There is an element 1 in S such that $a1 = 1a = a$ for all a in S
(M6) No zero divisors:	If a, b in S and $ab = 0$, then either $a = 0$ or $b = 0$
(M7) Multiplicative inverse:	If a belongs to S and $a \neq 0$, there is an element a^{-1} in S such that $aa^{-1} = a^{-1}a = 1$
